Abstract

The Arkansas Groundwater Protection and Management Report is produced annually by the Arkansas Department of Agriculture's Natural Resources Division (NRD) pursuant to the Arkansas Groundwater Protection and Management Act of 1991, Arkansas Code Annotated 15-22-906. This report provides a summary of groundwater protection and conservation programs administered by the NRD during the years 2022 and 2023, including water-level monitoring and studies of water use trends in the state.

This report focuses on aquifer level and water quality data collected by the NRD and its partners in 2023, but primarily features data from two major aquifers in the state, the Mississippi River Valley Alluvial Aquifer (alluvial aquifer), the most important water resource for agricultural production in the state, and the Sparta/Memphis Aquifer (Sparta), one of the state's best sources of good quality groundwater for drinking and industrial uses. Data collected from the Tokio and Nacatoch aquifers have also been included in this report. The report compares synoptic water-level data collected in the spring of 2023 to historical synoptic water level data; typically, in one, five, and ten-year intervals. This report also examines data collected continuously, monthly, and quarterly, to monitor the various aquifers responses to the stress conditions of 2022 and early 2023. Climate and water use data are considered along with water level data to explain the water level change results.

Aquifer-wide water level data collected during the pre-irrigation period of spring 2023 had positive average change values for both the alluvial and Sparta aquifers when compared to spring data from 2018 and 2013 but showed slight decreases in water level when compared to 2022. Maps depicting spring 2023 water level elevations and one-, five-, and ten-year water level change are presented in this report. Numerous water level hydrographs are also presented across both aquifers to illustrate water level trends over time. Long term trends in the Nacatoch and Tokio aquifers show that wells in both aquifers are experiencing water level decline in some areas but that the overall average change is positive for most of the areas that were monitored.

While we are seeing positive average change values in the five and ten-year intervals in this report, the general trend in Arkansas's long-term water level change is that the groundwater levels are declining. It is important to remember that, overall, Arkansas is withdrawing groundwater from the alluvial and Sparta aquifers in Eastern and Southern Arkansas at a rate above that which has been estimated to be sustainable. Some wells in certain areas where there have been historical declines do appear to show a slowing of the decline, or in some cases a rebounding trend in water level in recent years; however, it is difficult to determine the primary causes for the rebounding trends. It is speculated that above average precipitation in previous years, coupled with water conservation efforts and efficiency programs that have been implemented in recent years may be having the desired effect on the aquifers, but this has not been specifically studied. Further research and analysis of these areas and the many factors that determine their groundwater usage may give valuable guidance for future efforts to protect groundwater reserves. The Department of Agriculture should continue to work with partners to monitor these resources and promote conservation, education, and the conjunctive use of ground and surface water at rates that are sustainable for current and future water use needs.

Introduction

This report is prepared in accordance with Arkansas Groundwater Protection and Management Act of 1991, Arkansas Code Annotated 15-22-906 to provide the State of Arkansas with a comprehensive water-quantity and water-quality document to be utilized, along with the Arkansas Water Plan as a guide for water resources conservation and protection programs. It includes data, analysis, and recommendations for the groundwater protection and management program, as well as water well construction data.

This report focuses on the two most used aquifers in the state, the Mississippi River Valley alluvial aquifer (alluvial aquifer) and the Sparta/Memphis aquifer. Data collection for the program is dependent upon a strong partnership with other state, federal, and local water resources agencies. A monitoring schedule has been established to obtain data from the alluvial aquifer and the Sparta aquifer on an annual basis. Historically, each spring approximately 300-400 wells are monitored in the alluvial aquifer, and approximately 100-200 wells are monitored each year for water levels in the Sparta/Memphis aquifer. In 2023, water level data was collected from approximately 439 wells in the alluvial aquifer during the spring. In addition to the spring measurements, synoptic alluvial aquifer water level measurements are collected in the fall to gauge aquifer drawdown once irrigation has ended for the year. This fall water level collection is not as comprehensive as the spring effort, historically, but this year 264 wells were measured that shared data with wells measured in the spring. The number of wells monitored will vary from year to year depending on the resources available, well accessibility, and other factors.

There are areas of the state experiencing groundwater withdrawals of such magnitude that demand on the aquifer exceeds the sustainable yield, resulting in consistently falling groundwater levels and the development of cones of depression. These areas occur in both the Mississippi River Valley alluvial and Sparta aquifers. Water-level declines are consistently observed in areas where water use is highest, such as portions of the Grand Prairie study area and in the Cache study area for the alluvial, and in the South Arkansas study area for the Sparta.

In addition to the great effort to collect synoptic water level data in the alluvial and Sparta aquifers for groundwater quantity assessment, the state is interested in groundwater quality data in these aquifers and others across the state. The Arkansas Department of Agriculture's Natural Resources Division (NRD) collects groundwater quality data through a long-standing partnership with the US Geological Survey (USGS), who maintains the Groundwater Salinity and the Arkansas Masterwell Network programs. The Groundwater Salinity program is focused on collecting basic field parameters and chloride and bromide concentrations in an established well network in the alluvial aquifer and Sparta aquifer. The Masterwell Network is a long-term groundwater quality network that is comprised of 47 active wells and springs in 14 different aquifers across the state. See the Groundwater Quality section of this report for more information and sampling results from both of these programs in 2023.

Water Policy

Water resources policy in Arkansas was established in the Arkansas Water Plan, in which the NRD identifies conservation, education, and the conjunctive use of ground and surface water, along with the development of excess surface water, to meet future water use needs. It is hoped that protection of the state's groundwater resources can be achieved through these measures rather than management strategies that may require allocation of water. All water use strategies must consider the wise use of

our state's water resources while protecting the state's aquifers. The NRD recommends that the state moves toward a sustainable yield pumping strategy through conservation and utilization of Critical Groundwater Area designation where needed to focus resources. Designation as a Critical Groundwater Area fosters conservation by offering enhanced tax credit benefits for conservation practices through the state's Water Conservation Tax Credit Program, by increasing educational outreach, and by qualifying the area for federal programs and funding. A Critical Groundwater Area is a non-regulatory designation; regulation cannot be initiated without a new process involving legal proceedings, additional notice, and public hearings. Figure 1 presents the groundwater study areas, while Figure 2 presents the Critical Groundwater Areas as designated.

Arkansas Groundwater Study Areas

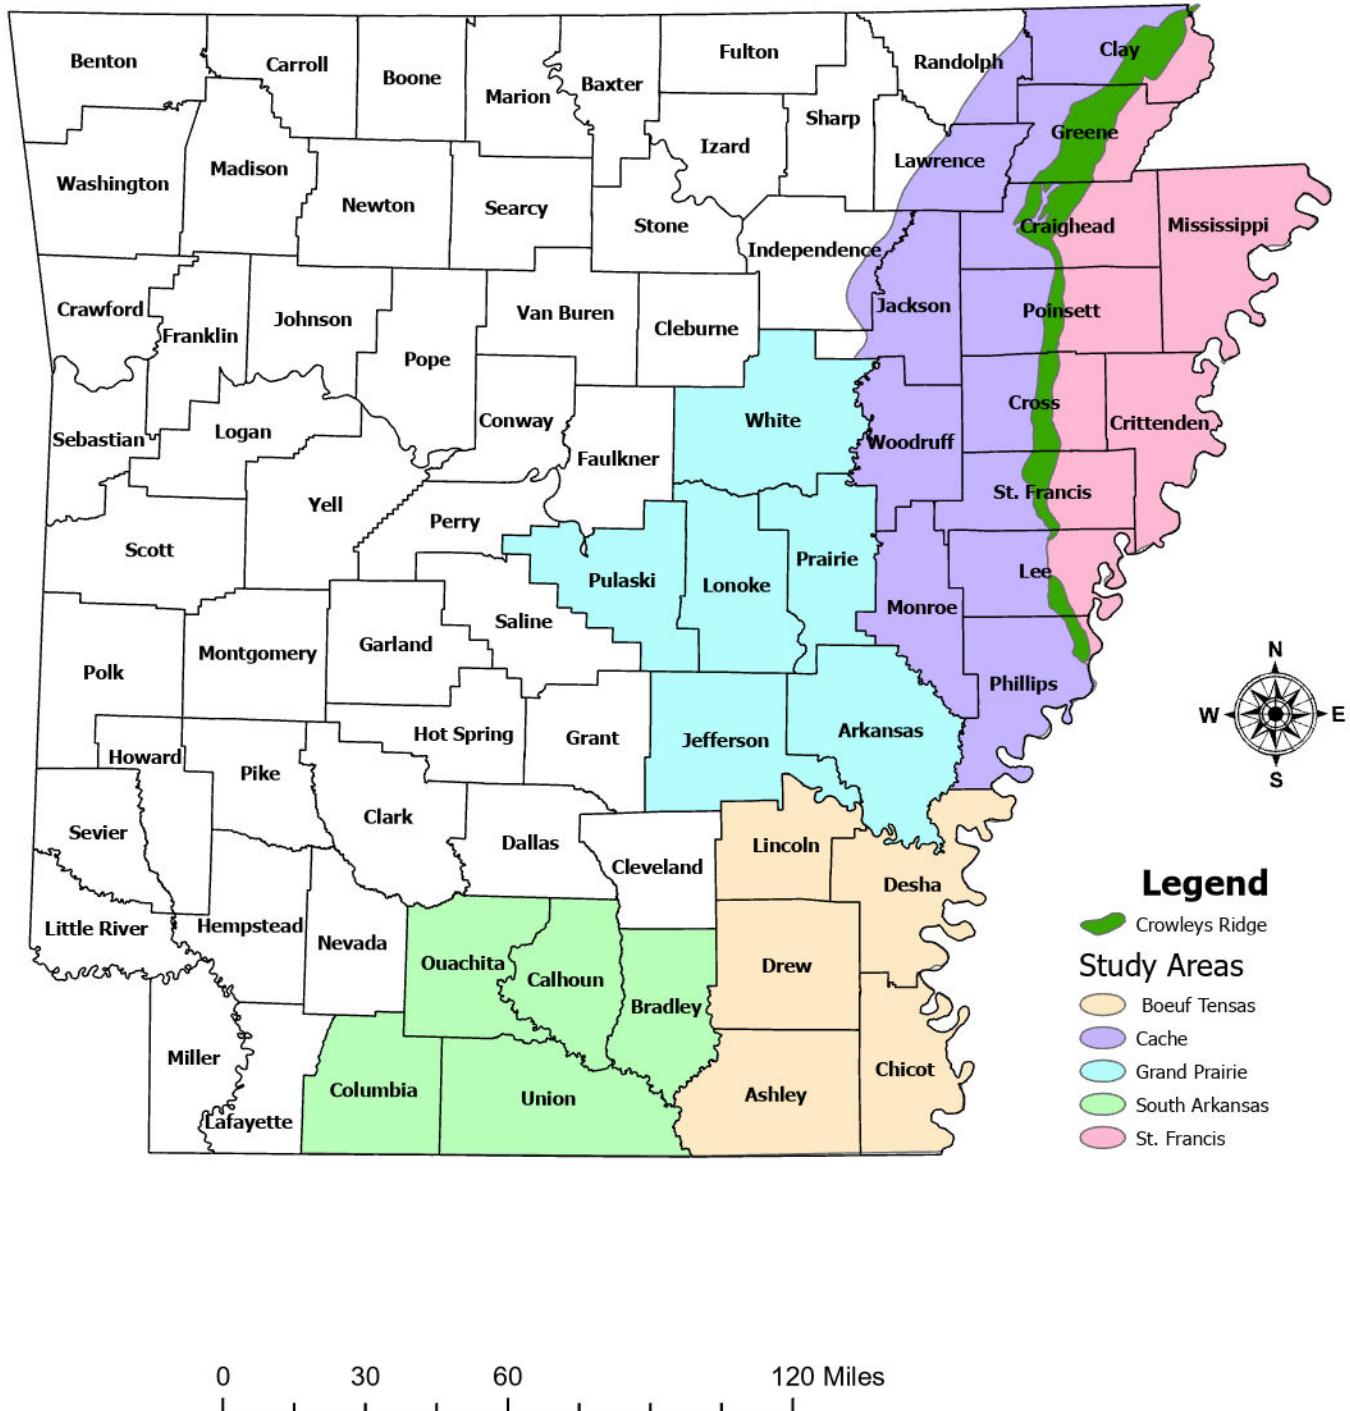

Figure 1

Critical Groundwater Areas

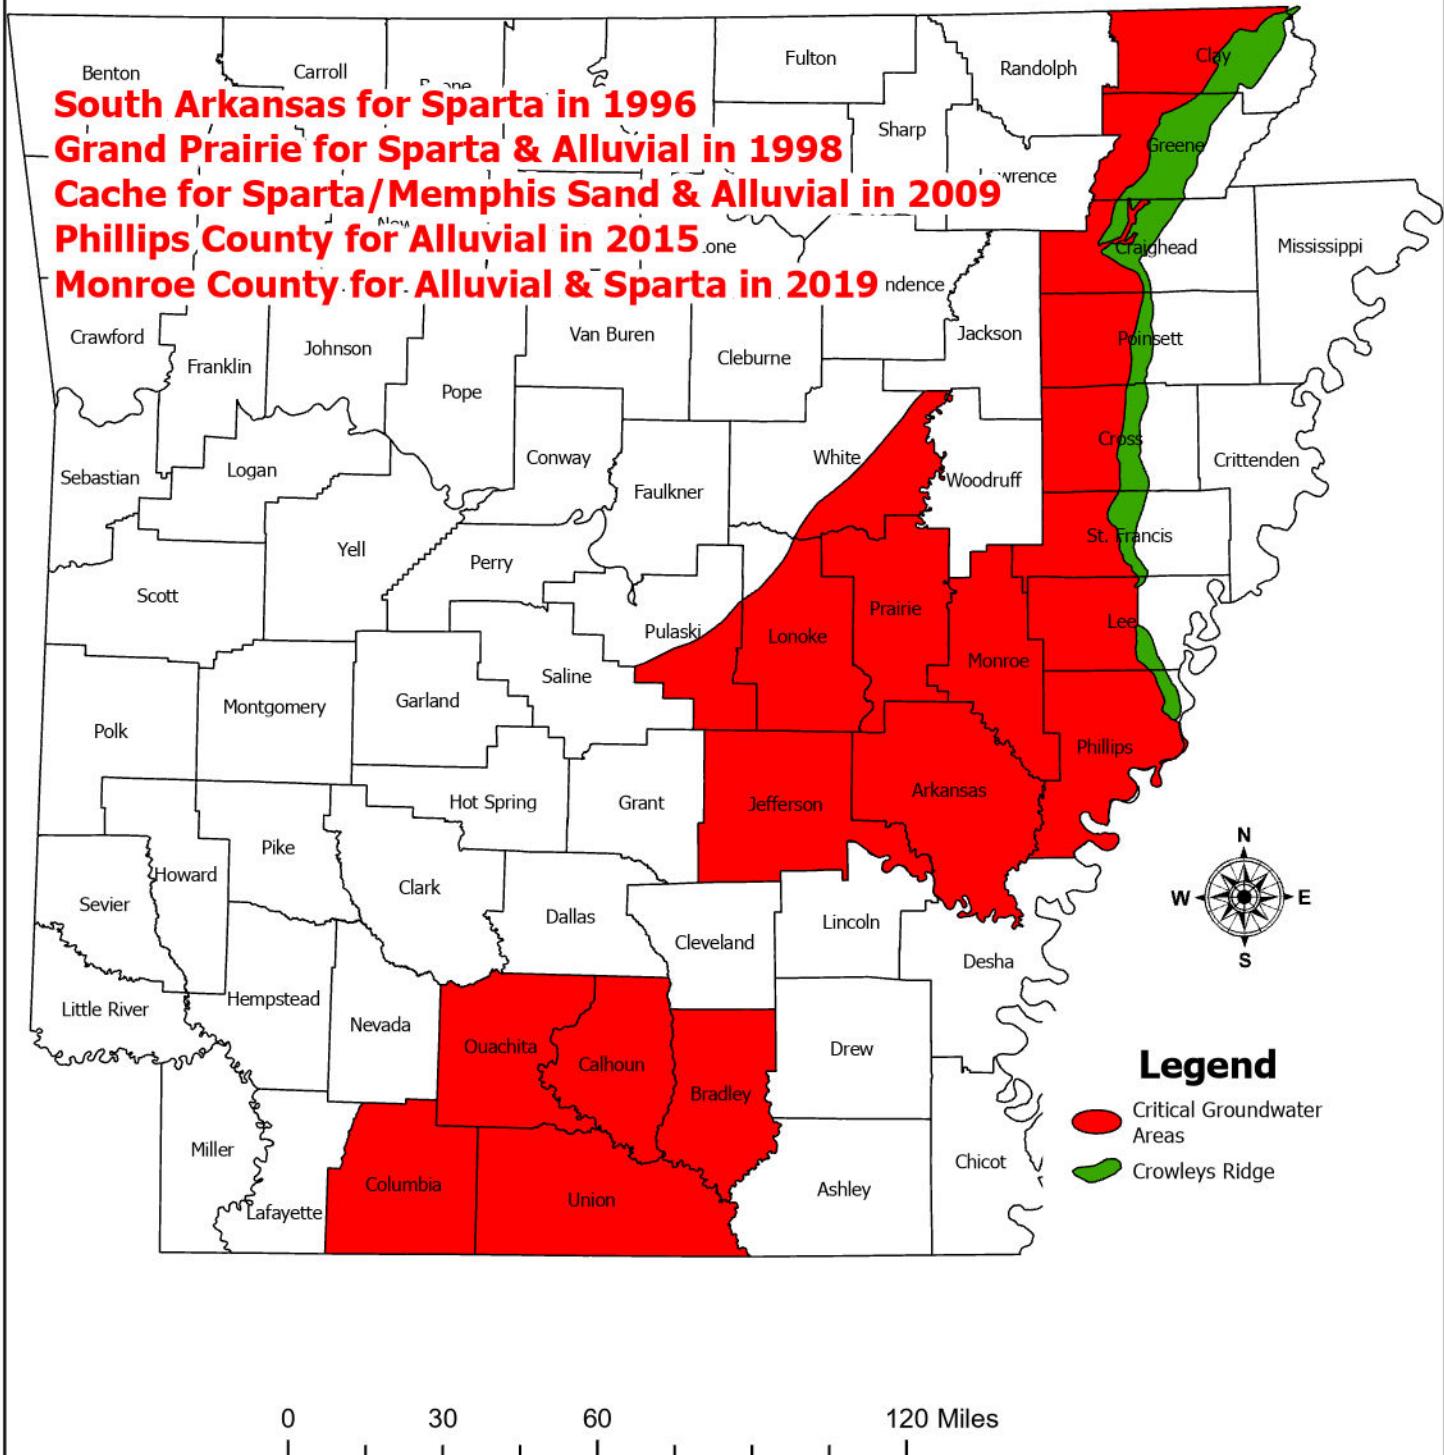

Figure 2

Hydrogeology and Water Level Trends

Mississippi River Valley Alluvial Aquifer

The Mississippi River Valley alluvial (alluvial) aquifer is the uppermost aquifer in the Mississippi Embayment and is composed of 50-150 feet of sand and gravel, grading from coarse gravel at the base to fine sand at the surface. It is generally overlain by the Mississippi River Confining Unit, which is composed of up to 50 feet of fine-grained sand, silt, and clay. For the purpose of this report, the term alluvial aquifer refers to the portion of the aquifer inside the state boundaries of Arkansas and the extent of the Mississippi River Alluvial Plain; generally, the fall line or contact with outcropping tertiary formations to the west, the Mississippi River to the east, and the state lines to the north and south. The alluvial aquifer is connected hydraulically with several rivers and drainage areas (Ackerman, 1996).

Static water level measurements were collected from 439 wells across the alluvial aquifer prior to the irrigation season in 2023, with most of the measurements being collected in April. Figure 3 presents the potentiometric surface data as altitude relative to mean sea level. Figure 4 presents the depth to water in the alluvial aquifer as feet below ground surface. Figure 5 presents the saturated thickness of the alluvial aquifer as a percentage of the total aquifer thickness. Saturated thickness values were calculated by subtracting the depth to water by the total aquifer thickness on a well-to-well basis. Aquifer thickness values were obtained from the United States Geological Survey (USGS) Scientific Investigations Map 3426 (Torak, 2019). The areas of greatest decline continue to be the historical cones of depression in the Grand Prairie and Cache River regions.

A significant change was made as to how saturated thickness values were generated for this report. In past reports, aquifer thickness values were obtained from the Mississippi Embayment Regional Aquifer System (MERAS) 2.0 USGS model (USGS, 2008). For this report, alluvial aquifer thickness values were obtained from the USGS Scientific Investigations Map 3426 (Torak, 2019). This change has resulted in some differences in the saturated thickness values than what has been previously estimated but should result in a more accurate estimation of aquifer thickness and saturated thickness values across the alluvial aquifer.

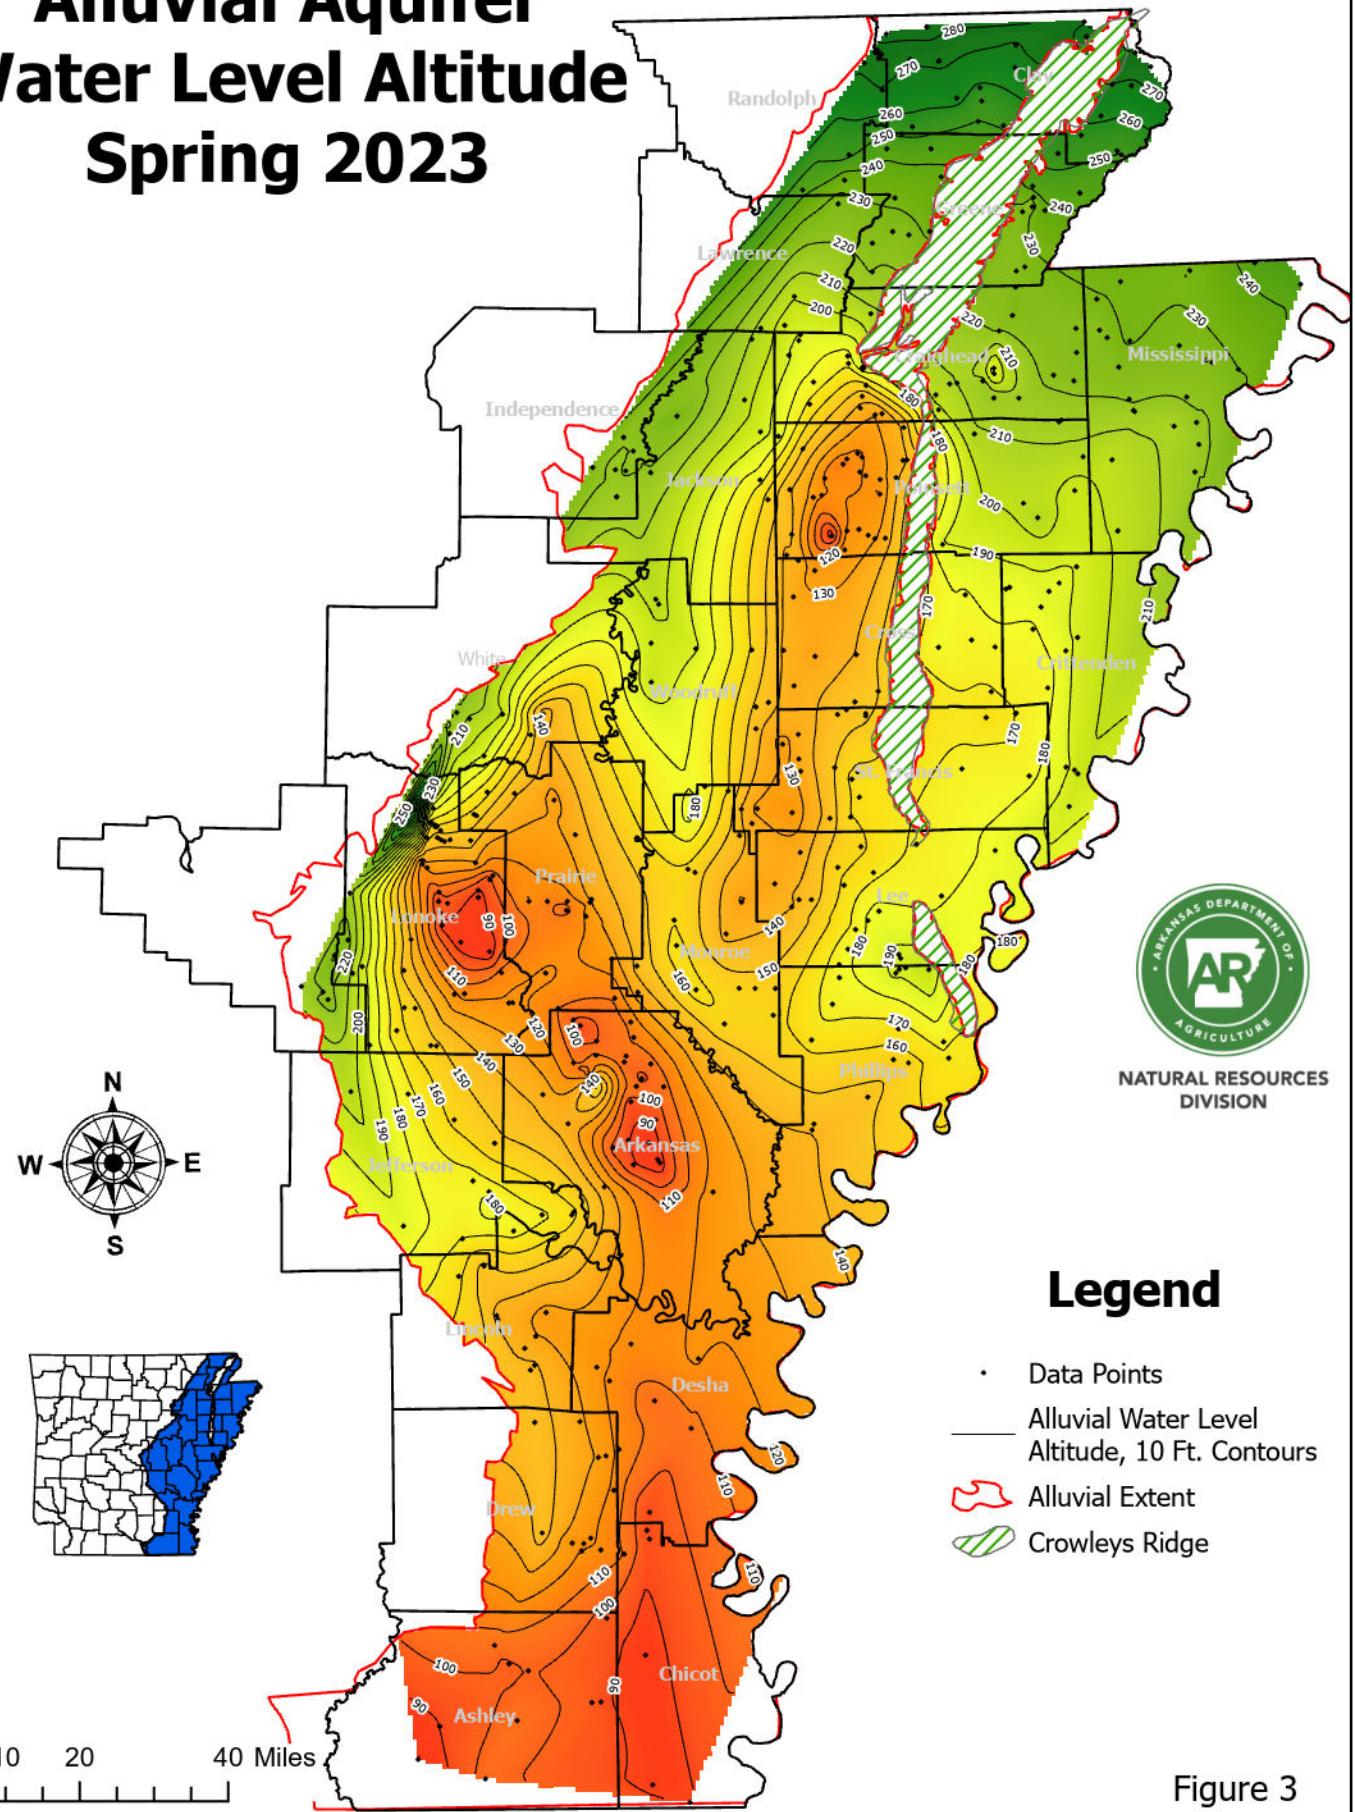

Within the Grand Prairie cone of depression, the updated thickness data and 2023 water level data shows that the area below 50 percent has widened, particularly in Jefferson and Arkansas counties; and the area under 20 percent saturated is significantly larger in Lonoke and Prairie counties, when compared with the saturated thickness values estimated in the 2022 groundwater report (NRD, 2023). In the Cache study area cone of depression, the new thickness data has estimated the alluvial aquifer to be slightly thicker than previously estimated resulting in higher saturated thickness numbers in much of the area using 2023 water level data. Craighead and Poinsett counties are still mostly below 50 percent saturated thickness, but the new data shows a significant decrease in the amount of area below 20 percent saturated in these counties. The largest differences in the Cache critical area are found in Cross and St. Francis counties. In the 2022 groundwater report, all of Cross County and a large portion of St. Francis County were estimated to be below 50 percent saturated thickness. This has now been reduced to only about half of what was previously below 50 percent saturated thickness in Cross county, and only a small area in the western toe of St. Francis is showing below 50 percent.

One of the most striking differences with the aquifer thickness data is in Ashley and Drew counties. In the 2022 groundwater report, only 2 wells located in central Ashley county had water levels below 50 percent saturated thickness. The new aquifer thickness values estimate the alluvial aquifer to be considerably thinner, and the 2023 water level data are now estimating that over half of Ashley County is less than 50 percent saturated with saturated thickness values as low as 20 percent over a

considerable area in the north central part of the county. The southwest corner of Drew County is estimated at less than 50 percent as shown in Figure 5; however, there are no actual water level data in this part of the county in these maps. Water level data will need to be collected in this area to verify the data presented here. The Arkansas Department of Agriculture's Natural Resources Division (NRD) will further research the aquifer thickness data in Ashley and Drew counties to ensure that these estimations are accurate for these areas.

There are research efforts by our USGS partners currently underway to refine the aquifer thickness estimates using advancements in subsurface modeling technology. Once this research is completed, we expect there will be minor changes to the estimates presented here, but it is also expected that the new estimations will be closer to the values used in this report, than the values from MERAS used in previous reports. Any further recommendations for these areas, such as a Critical Groundwater Area designation, will be made when the aquifer thickness values can be verified using the new subsurface modeling data.

NATURAL RESOURCES DIVISION

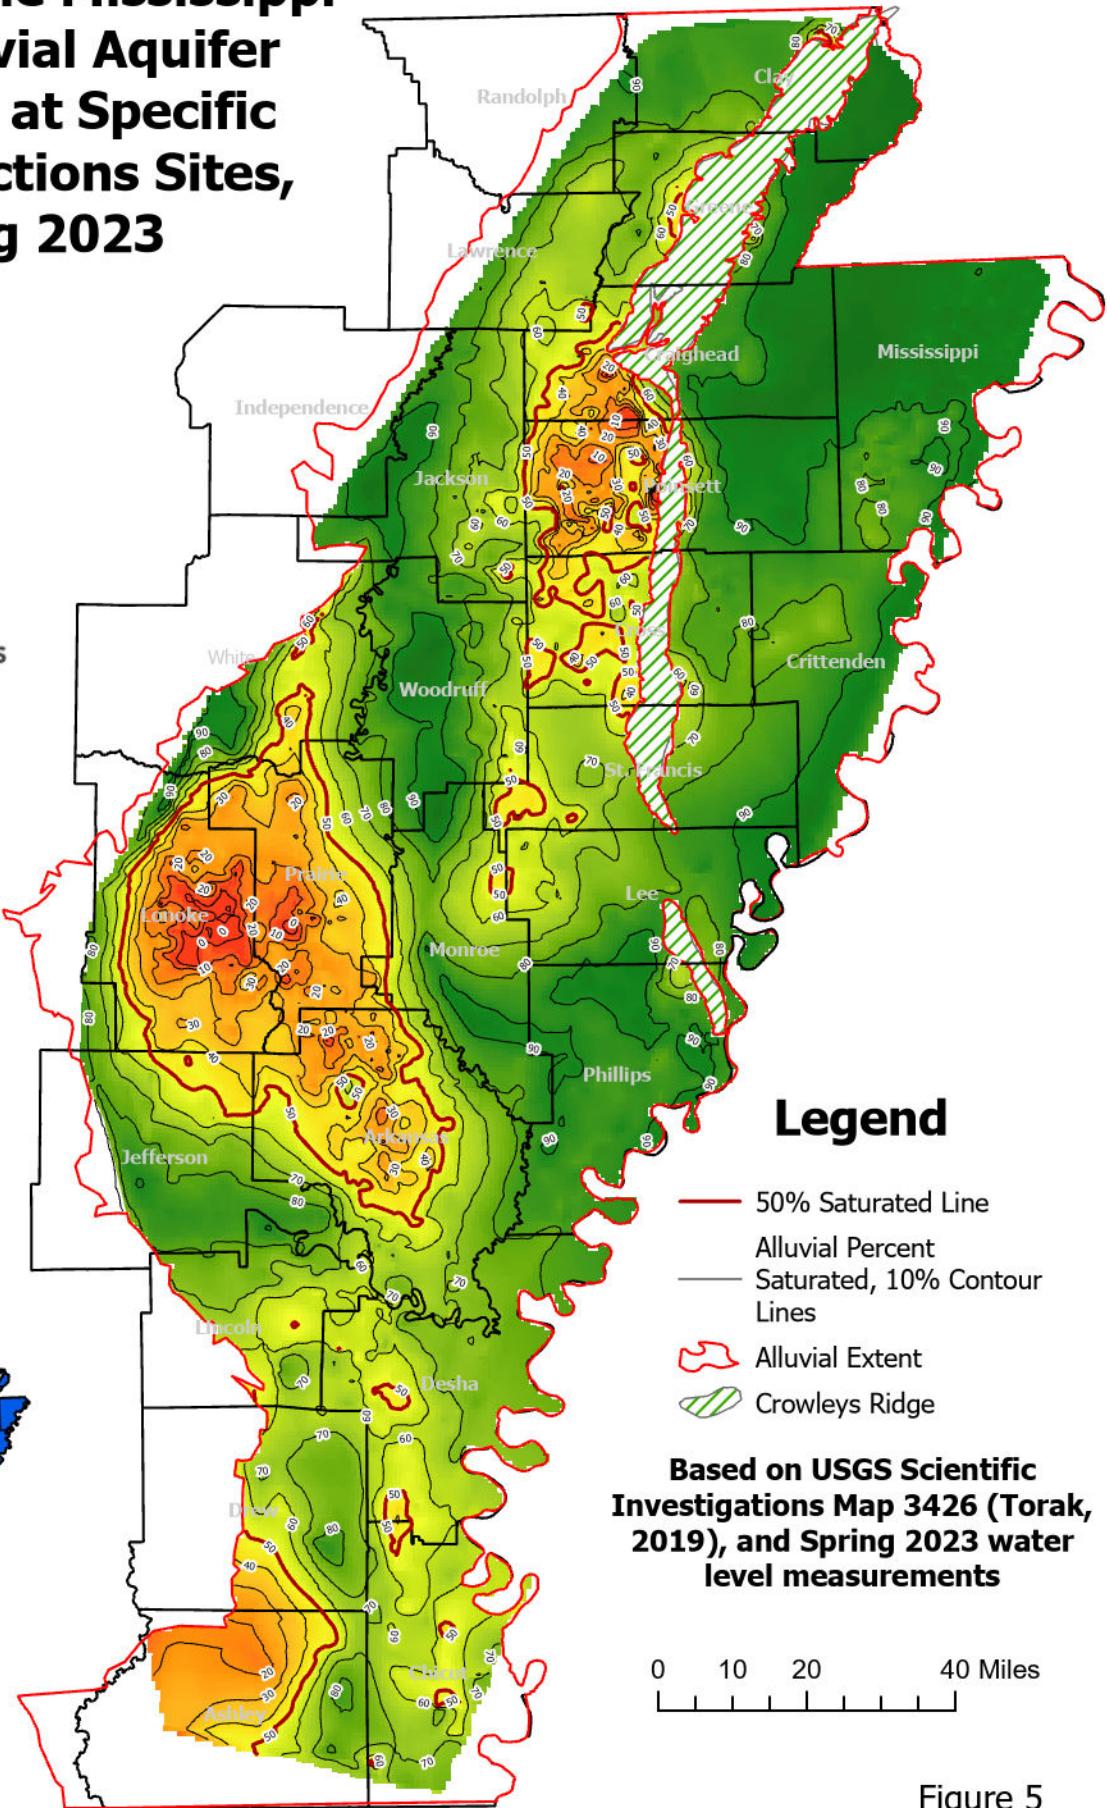

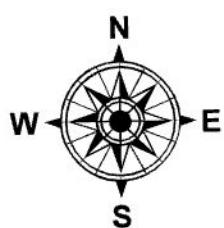

Figure 5

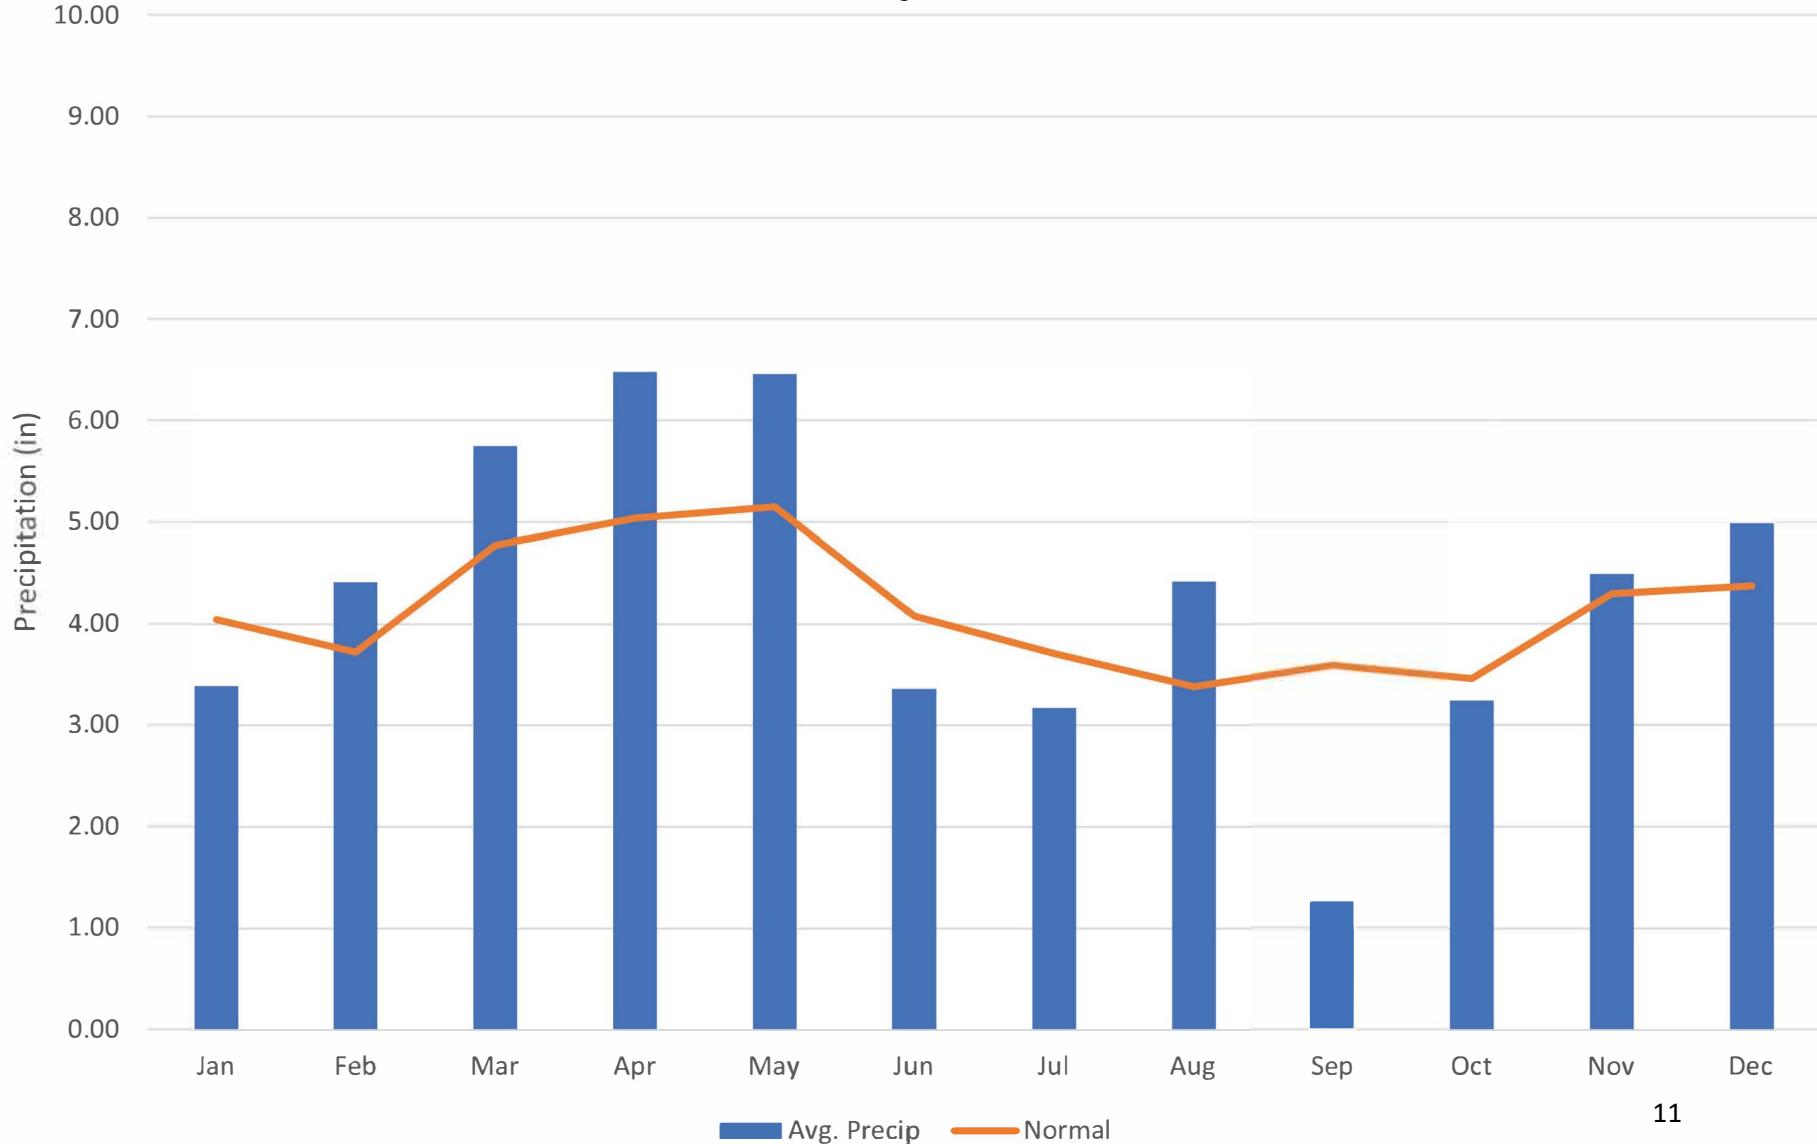

Precipitation and Weather Events

The amount of rainfall is considered for comparison with the water level change during times of drought or excess rainfall. Years of abundant precipitation benefit the alluvial aquifer by increasing the ability for the aquifer to recharge naturally and by reducing the demand for groundwater, especially adequate amounts of rainfall throughout the growing season (March through September). In 2022, the total average precipitation was 51.42 inches, 1.81 inches more than the annual average and 0.55 inches above 2021. During the 2022 growing season, most months had below average precipitation except for August, which was just above average, and May, which was significantly above average. Figure 6 shows the statewide monthly average precipitation for 2022 compared with the normal average monthly values.

Arkansas has received average to above average rainfall for most years since 2011. During this period, the average water level change across the alluvial aquifer has generally been trending upwards, with the notable exception of 2021. One year precipitation totals for 2022 represent the second year in a row of near normal rainfall but significantly below normal precipitation during the growing season. The spring 2022 to 2023 average water level change comparison exhibits a negative average change value of -0.7 feet. Figure 7 compares the statewide annual average precipitation to the average change in water levels in the alluvial aquifer from 1997 to 2022. Figure 8 presents data from the National Weather Service illustrating the total monthly precipitation received as a departure-from-normal value across the Mississippi River Valley Alluvial Plain for the 2022 growing season (NOAA, 2023).

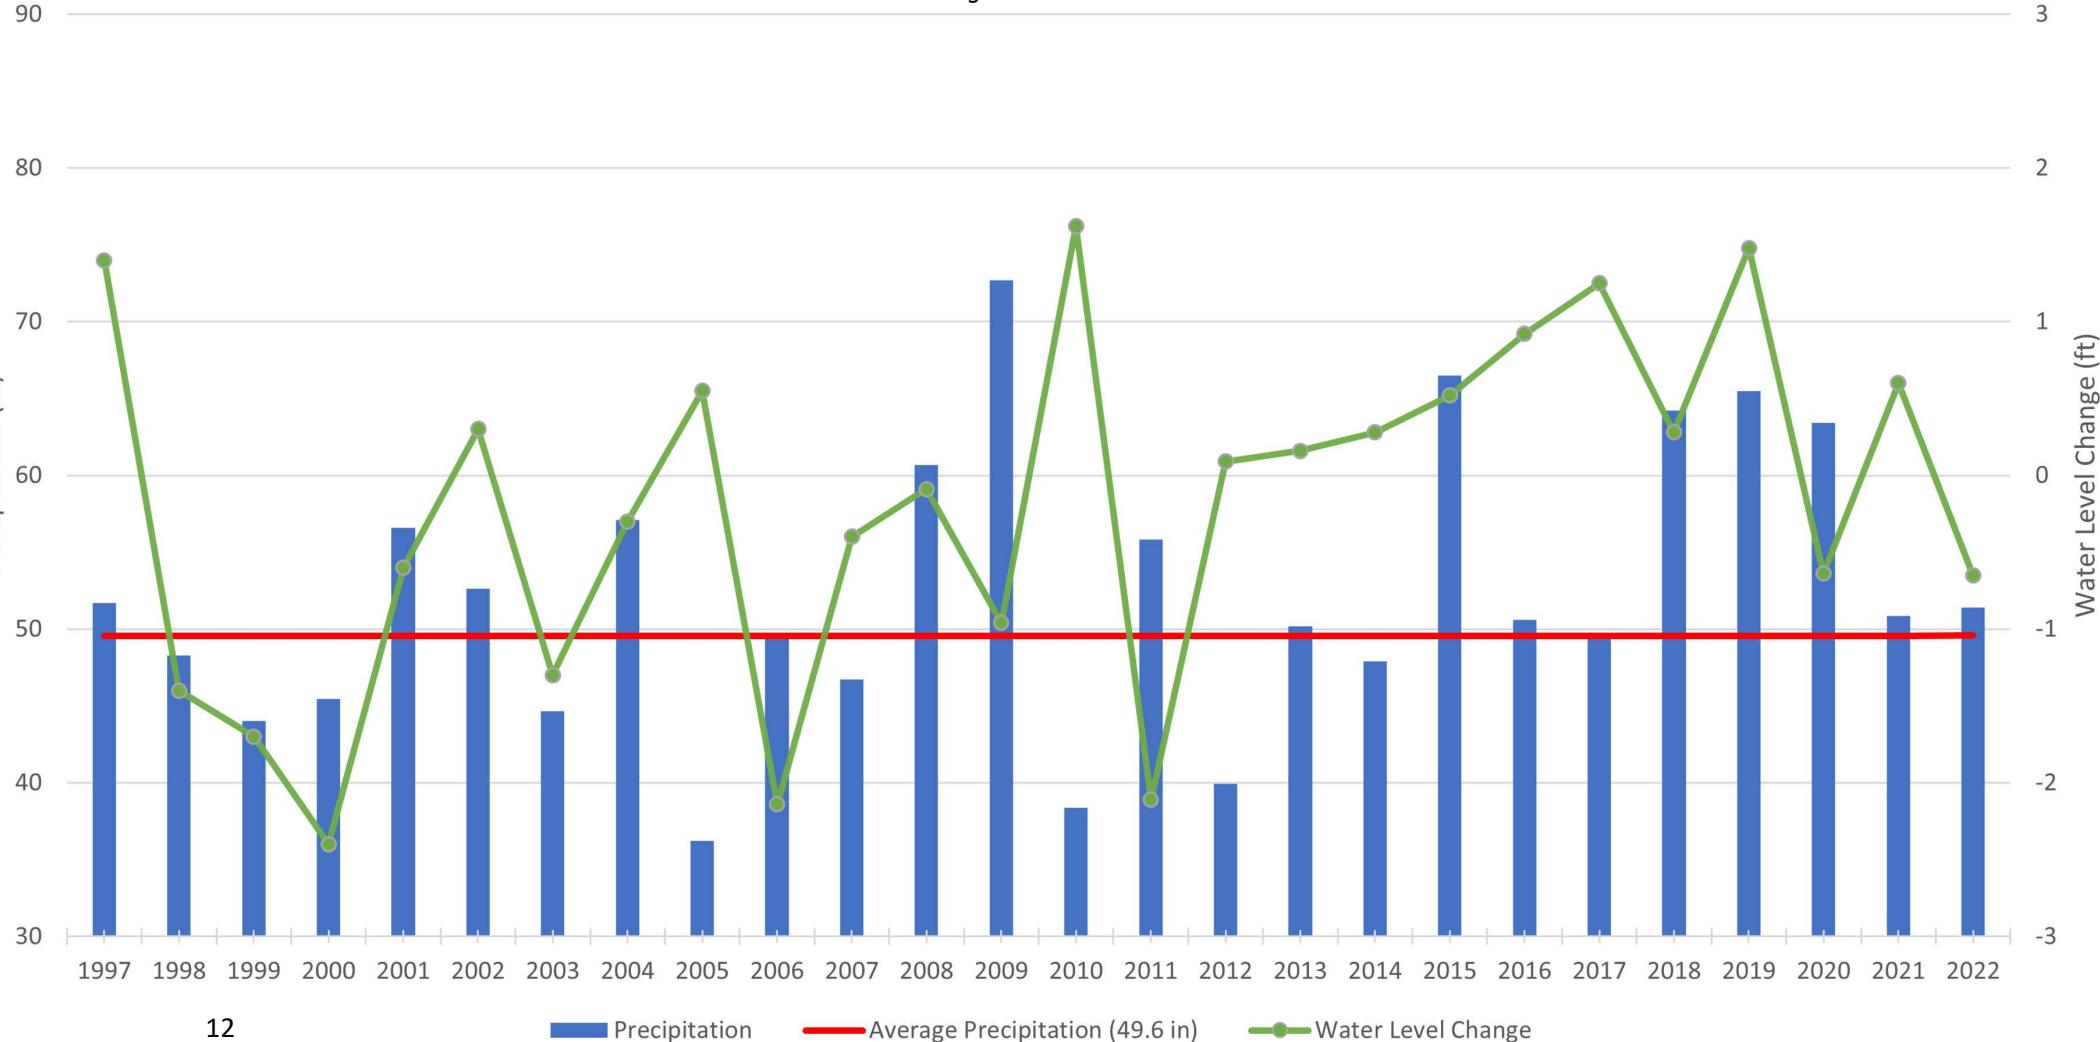

Average Monthly Precipitation, 2022

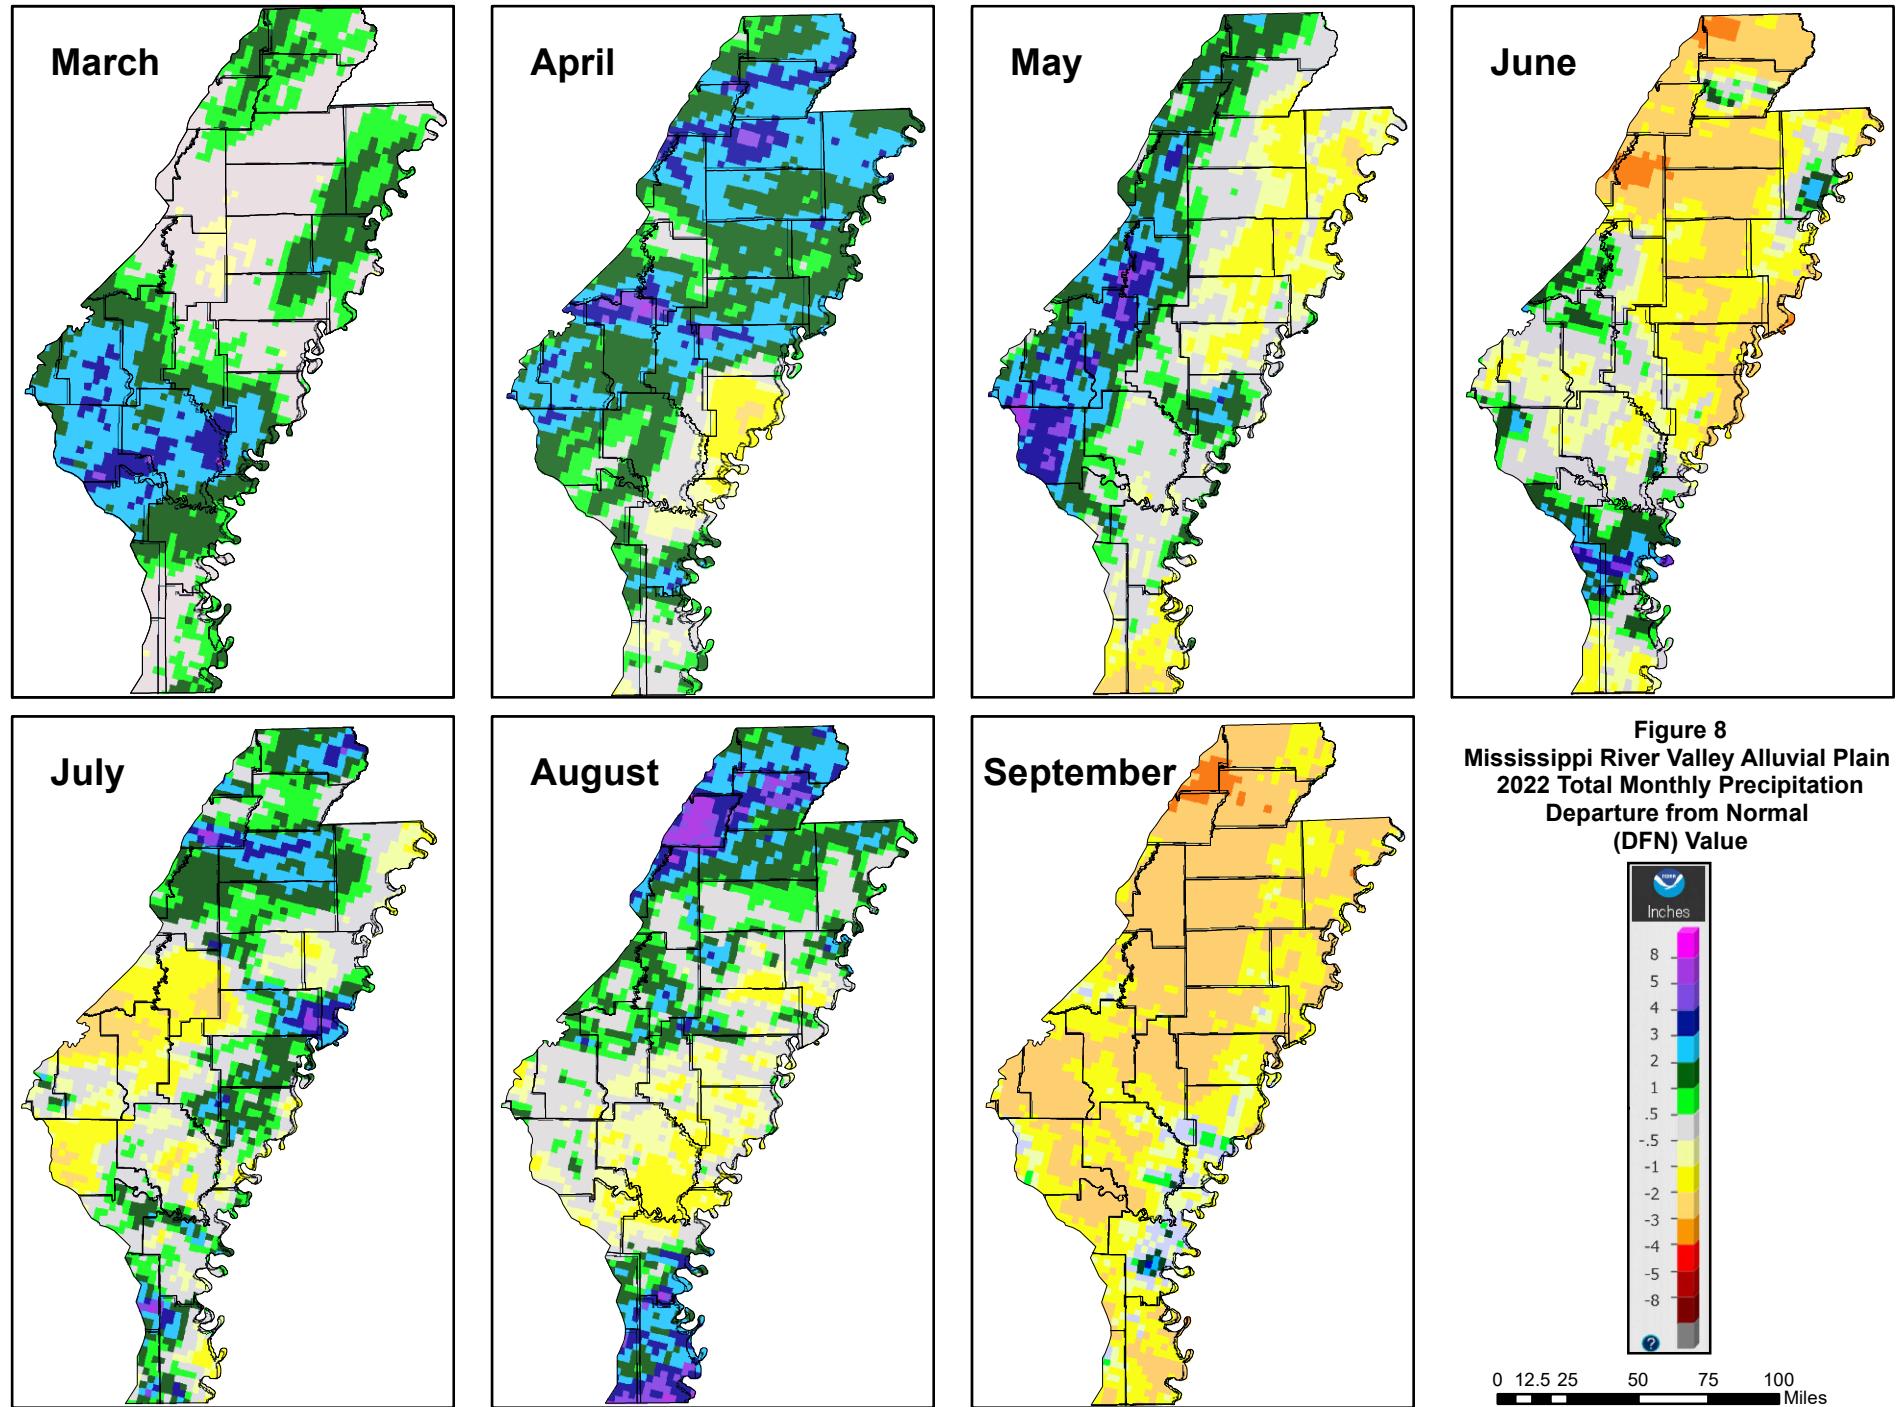

Figure 6

One Year Average Alluvial Aquifer Ground Water Level Change Vs. Average Annual Precipitation

Figure 7

Water Level Trends

Water level data from the current year are compared with previous data on a well-to-well basis in one (1), five (5), and ten (10) year intervals to illustrate the water level change of the aquifer over time. For the one-year change comparison, 332 of the 439 wells measured in spring 2023 shared data with the spring 2022 dataset, and when compared, give a total average water level change of -0.7 feet with 226 wells (68.07 percent) showing a decline in level. For the five-year comparison, 259 wells were identified as having data for both 2023 and 2018 giving a total average water level change of +0.41 feet with 107 wells (41.31 percent) having declining static water levels. The ten-year comparison found 159 wells with water level data for the spring seasons of 2023 and 2013 and gave a total average water level change of +2.46 with 37 wells (23.27 percent) compared showing declining aquifer levels.

Aquifer-wide water level change maps were created for the different time intervals: Figure 9 presents the one-year spring 2022 to spring 2023 water level change, Figure 10 presents the five-year spring 2018 to spring 2023 water level change, and Figure 11 presents the ten-year spring 2013 to spring 2023 change data. These maps show that water level declines continue to be primarily concentrated in the Cache and Grand Prairie areas where historical declines have been significant, particularly in the areas of the aquifer furthest from a major surface water source (e.g. the Arkansas, White, and Mississippi rivers). Conversely, the areas with increasing water level change values can generally be found along these sources. The five and ten-year change maps illustrate the movement of the existing cones of depression as Prairie and Lonoke counties continue to have declines in the Grand Prairie, and as the Cache depression continues to expand southward into Monroe and Lee counties. Some water level decline can be found in the Beouf-Tensas and St. Francis study areas in the one-year comparison, but these declines do not appear to be causing significant aquifer drawdown over time.

Approximately 264 alluvial aquifer wells were measured in the fall of 2023 that had also been measured during the spring. When compared, the total average change for spring to fall 2023 measurements was -4.06 feet, which is the highest average change calculated in a few years: 2018 (-3.57), 2019 (-2.90), 2020 (-3.32), 2021 (-2.80), and 2022 (-3.42). Figure 12 presents the spring to fall water level.

Selected water level hydrographs from the alluvial aquifer are presented on Figure 13; the well locations are shown on Figure 4. All of these hydrographs are from monitoring wells maintained by the Arkansas Department of Agriculture's Natural Resources Division or the USGS and are measured semi-annually or more during the year or have real-time data loggers installed for continuous water level data.

As previously mentioned, the spring 2023 water level change values showed a negative average change of -0.70 feet for the entire alluvial aquifer in the one-year period, while the five and ten-year periods had positive average values of +0.41 and +2.46, respectively. The aquifer-wide data has been focused on the four study areas that include the alluvial aquifer: Grand Prairie, Cache, St. Francis, and Beouf-Tensas, for each period. The 2023 data shows increasing average water level changes for most study areas for five and ten-year time periods but decreasing values for all study areas in the one-year comparison. Figures 14 through 25 depict the spring 2023 alluvial aquifer water level change data and well locations for the four study areas over the one, five, and ten-year change intervals.

Appendix A presents the 2023 aquifer water level data along with the 2013, 2018, and 2022 water level data for wells measured in 2023 as used in this report.

Sparta/Memphis Aquifer

The Sparta/Memphis (Sparta) aquifer, also known as the Sparta Sand, the Memphis Sand/Memphis aquifer, and the middle Claiborne formation, is a tertiary-aged water bearing assemblage composed mainly of sand with considerable amounts of silt, clay, shale, and lignite found in lenses throughout the unit. The formation outcrops along the western edge of the Mississippi Embayment in Southern Arkansas and is overlain by the Mississippi River Valley alluvial aquifer throughout Central and Northeastern Arkansas. The Sparta Sand is the thickest sand unit in the Mississippi Embayment system, ranging in thickness from zero to 200 feet along the outcrop and up to 900 feet in the southeastern part of the state. Generally, the Sparta Sand is a confined aquifer system as it is confined by the underlying Cook Mountain formation and overlying Cane River formation. Lithological differences occur in the Sparta aquifer in Southern Arkansas and Northeastern Arkansas. In Southern Arkansas, the Sparta aquifer is divided into two units; the Greensand (upper Sparta) and the El Dorado sand (lower Sparta), by a confining layer. In Northeastern Arkansas, the underlying Cane River and Carrizo Sand formations become sand and are generally indistinguishable from the Sparta Sand; because of this, the three formations are grouped together and referred to as the Memphis Sand, or the Memphis aquifer, in this region (Kresse, T. M., et al., 2014).

Groundwater levels were collected from 230 water wells in the Sparta aquifer during the spring of 2023. Figure 26 depicts the spring 2023 potentiometric surface as water level altitude in feet above mean sea level, and Figure 27 presents the depth to water as feet below ground surface for the Sparta aquifer.

Water Level Trends

Water level data from the 230 wells collected in spring 2023 were compared with historical data in one, five, and ten-year intervals. The one-year interval had 182 comparable wells giving a total average water level change of -0.73 feet with 109 (59.89 percent) of the wells in decline. The five-year change had data for 165 comparable wells with a total average change of +4.16 feet with 41 (24.85 percent) wells in decline. As for the ten-year interval, water level data was compared for 162 wells with total average water level change of +7.87 feet with 37 (22.84 percent) wells in decline. Aquifer-wide water level change maps were created for the one, five, and ten-year periods and presented as Figure 28, Figure 29, and Figure 30, respectively.

Selected water level hydrographs from the Sparta aquifer are presented in Figure 31 and illustrate the changes in water level overtime back to the early 2000s. These hydrographs correspond with the wells shown on Figure 27. All of the hydrographs in this figure are from monitoring wells maintained by the Arkansas Natural Resources Division (NRD), the Union County Water Conservation Board, or the United States Geological Survey (USGS) and are measured semi-annually or more during the year or have real-time data loggers installed for continuous water level data.

Overall recovery continues in the areas where historical drawdown has been the most significant in South Arkansas with the study area having positive average water level change values of +1.53, +7.14, and +11.74 feet in the one, five, and ten-year intervals, respectively. These values are very consistent with those presented in last year's report (NRD, 2022). The area of most significant recovery continues to be Union County where several wells have positive water level change values as much as 50 feet over the ten-year period. The historical depression in Jefferson County continues to rebound with significant increases in water levels observed throughout the county, particularly in the five and ten-year comparisons. Figures 32, 33, and 34 present the South Arkansas water level change data.

Declining water levels were observed in wells throughout the aquifer in each comparison, but there are some observable patterns. In the 1-year comparison, the western edge of the aquifer has a high concentration of declining water level values. This area is where the aquifer is the shallowest and close to, or in, the recharge zone for the aquifer. This pattern does not occur in the five and ten-year

comparisons in the southern part of the state, but it continues to be very noticeable in the northern portion, from Lonoke county extending up along the aquifer's extent into Craighead. There is a lack of data for the Sparta in the northeastern part of the state in the ten-year comparison; however, based on the pattern in the five and ten-year declines in Lonoke and Prairie county it is assumed that this declining trend would be observed in wells near the western extent of the aquifer in Cross, Poinsett, and Craighead counties, if there were wells with data to compare.

We believe that this pattern of water level decline is highlighting a change in the hydrogeologic structure of the region. Within the Lonoke and Prairie County area the Sparta aquifer goes from outcropping at the ground surface at its western extent to subcropping beneath the overlying alluvial aquifer deposits. In other words, the sediments of the Sparta aquifer directly underlie those of the alluvial aquifer with no significant confining unit or aquitard between them. It is our presumption that this pattern of long-term declining water levels in the Sparta aquifer along this trace is due to the stresses on the overlying alluvial aquifer along this area where the alluvial and Sparta aquifers are hydraulically connected.

Appendix B presents a table of specific water-level monitoring data for the Sparta aquifer from the 2023 monitoring period, as well as the one, five, and ten-year water level change data.

Tokio and Nacatoch Aquifers

In addition to the alluvial and Sparta/Memphis aquifers, the United States Geological Survey (USGS) also monitors lesser utilized aquifers throughout the state on a rotational basis. Every third year, the USGS monitors wells in the Cockfield and Wilcox, the Tokio and Nacatoch aquifers, and Paleozoic Age aquifers. The 2023 monitoring year was designated for the Tokio and Nacatoch aquifers.

Tokio

Static water level measurements were collected from 36 wells across the Tokio aquifer during the 2023 measurement season. Figure 35 depicts the 2023 potentiometric surface as water level altitude in feet above mean sea level.

Figure 36 shows a comparison of water level data from the current year on a well-to-well basis with a 12-year interval to illustrate the water level change of the aquifer over time. Overall, the aquifer declined -0.81 ft. over that time with 17 out of 31 wells (54.84 percent) showing declines. Wells with increasing aquifer levels are concentrated in the shallower parts of the aquifer along the northern extent, while the greater declining values occur in the southern and eastern extent where the aquifer is deeper.

Nacatoch

Static water level measurements were collected from 39 wells across the Nacatoch aquifer during the 2023 measurement season. Figure 37 presents the potentiometric surface as water level altitude in feet above mean sea level.

Figure 38 presents a comparison of water level data collected in 2023 with data from a 12-year interval. Overall, the aquifer increased +3.32 ft. over that period with 6 out of 31 wells (19.35 percent) showing declines. There does not appear to be a pattern with the 6 wells that experienced declines in the 12-year comparison.

Groundwater Quality

Our United States Geological Survey (USGS) partners contribute groundwater salinity data every year from a network of 100 wells, 50 in the Mississippi River Valley Alluvial aquifer and 50 in the Sparta-Memphis aquifer. This network is sampled on a rotation of 25 wells per year alternating years between the alluvial and Sparta aquifers. In 2023 field measurements from 25 wells in the Sparta were performed recording pH values, temperature, specific conductance, and concentrations of chloride and bromide. In 2024, 25 wells from the alluvial aquifer will be sampled per the contracted schedule. Results from the 2023 sampling event are presented below in Figures 39 and 40.

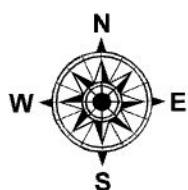

In addition to the Groundwater Salinity Program, the state is interested in monitoring other water quality parameters in other aquifers across the state. To achieve this, Arkansas Department of Agriculture's Natural Resources Division (NRD) partners with the USGS to maintain the Arkansas Masterwell Network program, a long-term groundwater quality network that is comprised of 47 active wells and springs in 14 different aquifers across the state. Each year five sites are sampled for a variety of water-quality constituents including common ions, metals, nutrients, and radiochemistry. In 2023, five different aquifers were represented by this sampling effort. The results can be seen in Figures 39 and 41.

Groundwater Use

Registered Wells

In accordance with Act 1051 of 1985, all wells in Arkansas that have the capacity to produce fifty thousand (50,000) gallons per day must be registered with the Arkansas Department of Agriculture's Natural Resources Division (NRD). Domestic wells are exempt. The quantity used must be reported by March 1st of the following year. The USGS reports that there are approximately 50,000 registered wells in the state and over 97 percent are agricultural wells used primarily for irrigation in Eastern Arkansas. The remaining approximate three percent of reported wells are used predominately for commercial, industrial, and public water supply purposes.

Reported Water Use

In 2015, an estimated total of 8,254.60 million gallons per day (Mgal/d) of water were reportedly withdrawn from all of the state's aquifers. The greatest reported volumes are from the Mississippi River Valley alluvial (alluvial) aquifer and the Sparta/Memphis (Sparta) aquifer, with approximately 7,636.08 Mgal/d being used from the alluvial aquifer and approximately 160 Mgal/d being used from the Sparta aquifer. The 2015 total water use data is still the most recent accurate figure for total water use across the state for various reasons; however, reported agricultural irrigation water use numbers for 2020 have been provided by the USGS.

Reported agricultural irrigation water use in 2020 estimates that a total of 5,583 Mgal/d of groundwater was used for irrigation from all aquifer sources in Eastern Arkansas, with 5,092 Mgal/d from 36,166 wells in the alluvial aquifer and 76 Mgal/d from 571 wells in the Sparta aquifer (USGS, 2022). This is a reduction of over 2,000 Mgal/d from the estimated agricultural irrigation water use in 2018 of 7,590 Mgal/d (USGS, 2019). In 2015, reported irrigation groundwater use is estimated to have been 7,434 Mgal/d from 48,410 wells in the alluvial aquifer. Based on these numbers, irrigation groundwater use from the alluvial aquifer in 2020 was approximately 2,342 Mgal/d less than in 2015 with 12,000 fewer wells reported. This reduction in reporting can be partially attributed to the pandemic and the related difficulties it caused that year, but the 2018 data used in previous reports also showed a considerable reduction from 2015. Reported irrigation groundwater use from the Sparta aquifer in 2020 increased by 12 Mgal/d from 2015 with 286 more wells reported.

The sustainable yield of the alluvial aquifer has been estimated at approximately 3,374 Mgal/d using the Mississippi Embayment Regional Aquifer Study (MERAS) modeling scenarios in which the aquifer was maintained at 50 percent saturated or 30 feet above the base of the aquifer, whichever was greater (Clark, B.R., Westerman, D.A., and Fugitt, D.T., 2013). Based on this sustainable yield, approximately 66 percent of reported 2020 irrigation groundwater use is sustainable using an incomplete, conservative estimate. Regarding the Sparta aquifer, 2020 irrigation water use estimates of 76 Mgal/d would account for approximately 86 percent of the estimated sustainable yield of 87 Mgal/d. This sustainable yield estimate is derived from USGS conjunctive use optimization modeling where drawdown constraints were defined as the hydraulic head at the top of the Sparta aquifer formation where the formation is confined and the hydraulic head at 50 percent saturated along the outcrop areas (McKee, P.W., Clark, B.R., and Czarnecki, J.B., 2004).

Historically, counties that report the largest groundwater withdrawals from the alluvial aquifer are the same counties with groundwater depletion issues. Arkansas, Lonoke, Poinsett, Woodruff, Clay, Desha, and Cross counties used the most groundwater for irrigation, based on 2020 reported water use numbers. This is mostly consistent with the areas of significant drawdown in the alluvial aquifer. Figure 42 presents the 2020 agricultural irrigation water use as reported at the time of this report.

In consideration of the significant reduction in stations reporting in 2020 when compared to 2015, an effort was made to estimate the change in usage if reporting numbers were similar. Figure 43 shows the 2020 reported usage per county in Mgal/day. A graph comparing the number of stations reporting water use data from 2015, 2018, and 2020 can be seen in Figure 44.

Using this information, Figure 45 was created presenting the change in number of stations reporting between 2015 and 2020, as well as calculating the average usage per station in each county in Mgal/day. This allowed for creation of estimated usage numbers for each county based on the average reported use per station. These values are approximate and cannot be considered exact representations of usage, but they may give a closer to accurate estimate of irrigation water use per county in 2020. Figure 46 gives the projected water use per county for 2020 by combining actual reported use with estimated usage as described. In this analysis, several counties in critical areas of interest are shown to have significantly underreported usage.

Based on this estimated data we can compare the 2015 total agricultural irrigation usage number reported of 8,240 Mgal/day to the 2020 reported of 5,583 plus the average estimated usage of 2,443 Mgal/day, giving a total for 2020 of 8,026 Mgal/day, suggesting a decrease in usage from 2015 to 2020 of 214 Mgal/day. While merely an estimate based on averages, this information demonstrates the importance of increased reporting on accurate usage data and concurrently our ability to quantify the value of conservation methods on overall water usage and aquifer levels.

Figure 47 presents the 2020 water use reported per crop type for the state. The pie chart shows the percentage of total reported groundwater use per crop. The principal agricultural uses of groundwater in the state are for poultry watering and rice, soybean, corn, and cotton irrigation.

Water Conservation Tax Incentive Program

The Water Conservation Tax Incentive Program encourages water users to invest in water conservation practices by offering a tax credit equal to 25 percent (statewide) or 50 percent (in a Critical Groundwater Area) of the cost to implement the practice. The following water conservation practices are eligible for tax credits:

- The construction of impoundments to utilize available surface water and reduce our dependence on groundwater;
- The conversion from groundwater use to surface water use when surface water is available;
- Land leveling to reduce agricultural irrigation water use; and
- The installation of water meters to monitor groundwater usage.

Figure 48 shows the locations of the water conservation projects that were approved for a tax credit for the years 2016 through 2023. A summary table of the number and types of conservation practices approved for a tax credit can be found below.

	Impoundments	Land Leveling	Surface Water Conversion	Water Meter Installations	Totals
2016	22	64	10	0	96
2017	12	45	8	0	65
2018	13	22	15	23	73
2019	9	27	12	9	57
2020	7	29	10	80	126
2021	15	43	10	7	75
2022	3	42	7	27	79
2023	13	64	12	0	89

In 2023, 89 projects were approved, 10 more than were approved in 2022. Land leveling constituted the largest number of these projects (64), but there were also significant increases in impoundments (13) and surface water conversions (12). These 89 projects created a near doubling of total land acres covered by groundwater tax credit conservation practices with 13,227.20 acres covered in 2023 compared to 7,077.36 acres in 2022. All these projects are critically important parts of the effort to sustainably manage groundwater resources.

Summary

The 2023 Groundwater Protection and Management Report is a summary of the activities and significant findings of the Arkansas Department of Agriculture's Natural Resources Division (NRD) Groundwater Section staff. This report is prepared annually in response to legislative mandates that direct the NRD to study the state's groundwater resources.

The purposes of the programs outlined in this report are to monitor the condition of the state's groundwater resources and to evaluate trends in water level and water quality fluctuations. The NRD, the United States Department of Agriculture Natural Resources Conservation Service, and the United States Geological Survey (USGS) monitor up to approximately 1,000 water wells each year for water levels and prescribed water quality parameters. This monitoring is accomplished through a cooperative agreement with the NRD and the USGS.

In the Mississippi River Valley alluvial (alluvial) aquifer, 439 water wells were measured in the spring of 2023, most of which were collected during the month of April prior to irrigation stresses during the growing season. As in previous reports, the spring 2023 data was compared with historical spring data in one, five, and ten-year intervals, and average water level change values were calculated to generally represent the water level trend over time. For the one-year comparison, 2022 to 2023, an average water level decrease of 0.7 feet was calculated. For the five-year comparison, 2018 to 2023, and the ten-year comparison, 2013 to 2023, average water level changes of +0.41 feet (five year) and +2.46 feet (ten year) were calculated. The spring to fall 2023 data comparison resulted in an average water level change of -4.06 feet, which is relatively consistent with the changes calculated in recent years. The areas with the most severe groundwater declines continue to be the Grand Prairie and Cache River study areas, particularly in the areas of the aquifer furthest from a major surface water source (i.e. the Arkansas, White, and Mississippi rivers). Water level decline in the Cache River study area continues in the southern part of the area moving into St. Francis, Monroe, and Lee counties. Some water level decline has been observed in the St. Francis and Beauf-Tensas study areas, but it is unclear if these declines are causing significant aquifer drawdown at this time.

These results show a positive average change in the five and ten-year trends representative of an overall rebound in aquifer water level, but a negative average change in the one-year. The decrease in the one-year comparison of -0.7 feet is a reversal of the positive change in the one-year value in the 2022 report of +0.6 feet. Being that these are simple comparisons of synoptic water level data from one year to another, it is difficult to explain definitively what causes these changes in trends. Changes in the timing and span of collected datasets in recent years lend to more accurate illustrations of the aquifer levels and will continue to do so for years to come as similar datasets are collected. However, it is important to keep in mind that this is limited data and that the year-to-year change comparisons are average numbers representing a large dataset in a complex and dynamic system.

In the Sparta/Memphis (Sparta) aquifer, 230 synoptic water level measurements were collected for the spring 2023 dataset. When compared with historical spring data, the 2023 data shows average water level change values of -0.73, +4.16, and +7.87 feet in the one, five, and ten-year intervals, respectively.

The Sparta aquifer in the South Arkansas study area continues to see recovery where historical drawdown has been the most severe. Union County continues to experience the most recovery, having the greatest average change in the five and ten-year intervals. The historical cone of depression in Jefferson County is recovering with significant rising water level values across the county in the time periods compared in this report. An apparent long-term pattern in declining Sparta levels is observable near the western extent of the aquifer where the alluvial and Sparta aquifers are hydraulically

connected. It is presumed that the over-production of the alluvial aquifer is impacting the underlying Sparta aquifer in this area.

While we are seeing positive average change values in the five and ten-year intervals in this report, it is important to remember that, overall, Arkansas is withdrawing groundwater from the alluvial and Sparta aquifers in Eastern and Southern Arkansas at a rate above that which is estimated to be sustainable. Wells in certain areas where there have been historical declines do appear to show a slowing of the decline, or even a rebounding trend in water level in recent years, but it is difficult to determine what the primary causes are for rebound trends in these areas. It is the hope of the NRD that the water conservation efforts and efficiency programs that have been implemented in recent years may be having the desired effect on the aquifers. Further research and analysis of these areas and the many factors that determine their groundwater usage may give valuable guidance for future efforts to protect groundwater reserves. The NRD should continue to monitor these resources and promote conservation, education, and the conjunctive use of ground and surface water at rates that are sustainable for current and future water use needs.
